Information

Percentages may not add up exactly to 100 due to rounding

Children are patients under 18 years of age, adults are patients aged 18 or more.

Cystic Fibrosis

Cystic fibrosis is a hereditary disease with autosomal recessive transmission: only subjects who have inherited two mutations – one from the father, the other from the mother – are affected.

The gene responsible for the disease was identified in 1989. It is located on the long arm of chromosome 7 (7q31) and codes for the CFTR protein, a protein involved in the regulation of chloride ion transport across the cell membrane. To date, more than 1,600 mutations have been identified, the most common (encountered in 80% of patients) is the F508del mutation.

Before implementation of the systematic newborn screening program, the most common context for diagnosis was as follows: alerted by clinical symptoms (steatorrhoea, bronchial obstruction, recurrent respiratory infections), the physician would carry out a sweat test. An elevated sweat chloride ions concentration would confirm the diagnosis, and this would be followed by molecular analysis of the *CFTR* gene and determination of the disease causing mutations.

Newborn screening has been systematic in France since 2002. This decision was taken by the Ministry of Health, which entrusted the task to the French association for screening and prevention of disabilities in children (*AFDPHE - Association Française pour le Dépistage et la Prévention des Handicaps de l'Enfant*). The screening technique uses measurement of immunoreactive trypsin (IRT) in the blood at age 3 days and detection of *CFTR* mutations. The IRT protein is more abundant when there is pancreatic abnormality during foetal life and in the first few months of life. Measuring IRT concentrations enables 95-98% of newborn children with cystic fibrosis to be detected, though the test is not specific enough (it picks out some children who do not have cystic fibrosis) and is therefore linked with a molecular analysis.

After looking for the main *CFTR* mutations (F508del and about thirty others), three situations can arise:

- two mutations are identified. The newborn baby and its parents are asked to visit a cystic fibrosis care centre (*CRCM - Centre de Ressources et de Compétences de la Mucoviscidose*) to confirm the diagnosis based on a clinical assessment and a positive sweat test, and to initiate the necessary treatment and monitoring ;
- a single mutation is identified (the probability of not identifying a second mutation is around 15%). The sweat test must be carried out in a specialised centre. If the test is positive, the child is treated in the same way as the previous group. If the test results are negative, information concerning the heterozygous nature of the newborn will be given to the parents during genetic counselling ;
- although the IRT level is high, no mutation is found. The risk that the child has cystic fibrosis is, in this case, below 1%. A second blotting paper sample test is carried out at age 21 days. If a raised IRT level persists at D21, the child is referred to a specialised centre for an additional assessment (sweat test).

On the pathological level, functional abnormalities occur in the digestive tract, the respiratory tract, the sweat glands and the genital tract. This wide range of abnormalities is associated with a broad spectrum of clinical expression, both regarding the age when the first symptoms appear and their subsequent evolution. The severity of respiratory symptoms affects life expectancy in the majority of cases.

Lifelong treatment is time consuming, demanding and aimed at symptomatic relief. It is essentially based on respiratory management (physiotherapy, antibiotic treatment, oxygen therapy, lung transplant for end stage respiratory disease) and digestive and nutritional management (pancreatic enzyme supplements and a hypercaloric diet).

The French Cystic Fibrosis Data Registry

In 1992, the medical Council of the association *Vaincre la Mucoviscidose*, set up a national cystic fibrosis observatory, the *Observatoire national de la mucoviscidose* (ONM), with the following objectives:

- improving knowledge on medical and social characteristics of the population with cystic fibrosis and the impact of therapeutics;
- gaining a better understanding of the socioeconomic cost of this disease with a view to obtaining sufficient resources to cover constantly growing needs;
- improving information available to help both parents and patients in their personal choices, and associations and other institutional partners in strategic decisions.

Covering the entire population of patients in France, has since been added to the initial objectives. The association has therefore transformed the ONM into a national cystic fibrosis registry, the *Registre français de la mucoviscidose*. This initiative was approved in July 2006 by the committee for protection of personal data in medical research (*Comité Consultatif sur le Traitement de l'Information en matière de Recherche dans le domaine de la Santé*, CCTIRS) and in March 2007 by the data protection agency (*Commission Nationale de l'Informatique et des Libertés*, CNIL). At the end of 2008 and then in 2011, the registry was certified by the national committee of rare disease registries (*Comité National des Registres Maladies Rares*), an organ of the *Institut de Veille Sanitaire* (InVS) and of the *Institut National de la Santé et de la Recherche Médicale* (INSERM).

The population is composed of people with cystic fibrosis followed in the care centres participating in the registry in France (metropolitan France and Reunion Island). Data are collected once a year by means of a questionnaire transmitted using Web, paper questionnaires or exports from electronic patient files. The information requested refers to the preceding year and includes semi-anonymous patient identification, diagnosis, medical follow-up, treatments used, anthropometric data, respiratory function, bacteriological data, evolution of the condition and social and family situation. Statistical analysis is performed on anonymized data.

Unless otherwise indicated, the results presented hereafter relate to the population seen during the year 2010 and were produced by cross-sectional analysis of data. Data on patients seen during the year in at least two centres were processed differently. Patients in this category (said to have multiple accounts) were counted only once and allocated to the centre they visited most often during the year.

Read precautions before use

Comparisons between the indicators from different countries must be done with care, due to a number of bias coming from the implementation of newborn screening programs, transplantation frequency, socioeconomic status and a limited number of patients in some age groups.

Median age (years)	16	16	17	16	17	16

French CF Registry - Annual Data Report 2010

Figure 2. Population pyramid

French CF Registry - Annual Data Report 2010

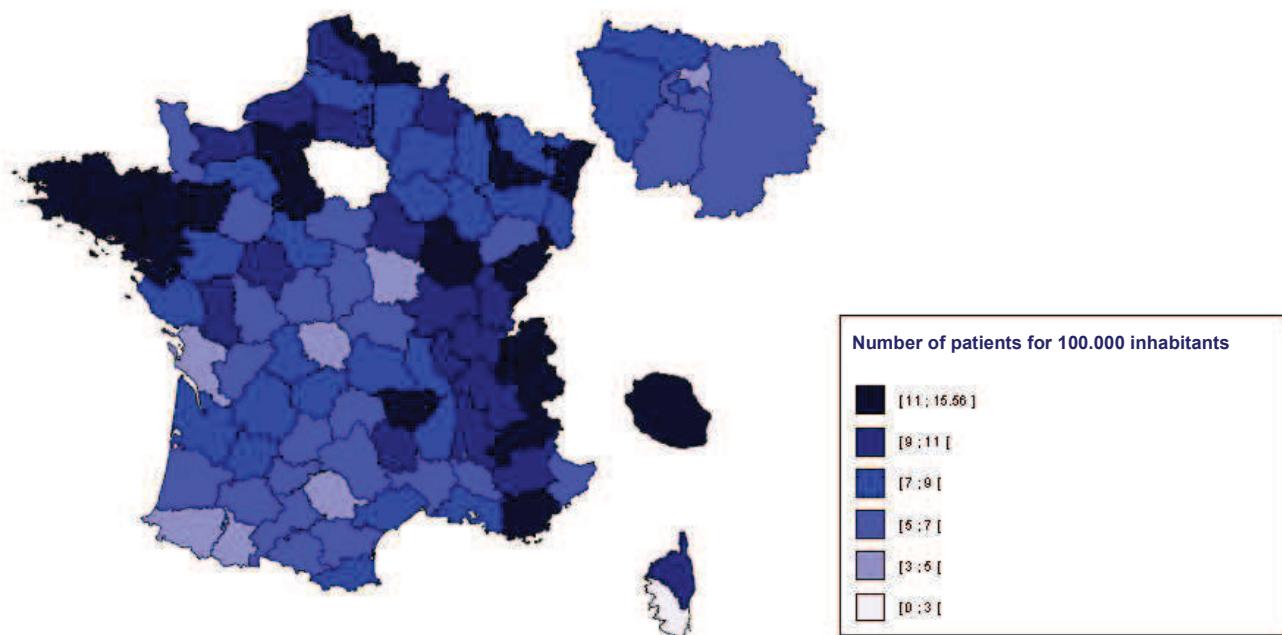

A total of 111 patients are aged below 1 (0 year completed age). Entry into the registry is delayed the first year of life as a certain number of infants diagnosed through neonatal screening in a given year are not registered until the following year.

As an indicative reference, 14 children born in 2009 (of whom 7 in December) were diagnosed by neonatal screening in 2010. On the 2009 population pyramid, the number of patients aged 0, which stood at 162, could thus have been $162 + 14 = 176$.

* Information of the death transmitted while the patient did not visit any centre during the year.

Mortality

Survival analysis

Figure 4. Survival curves by birth cohort (Kaplan-Meier method)

Population : patients seen by participating centres and patients lost to follow-up.

In order to show the evolution of health status of the patients, a survival analysis was performed on 4 birth cohorts; the numbers of patients and of deaths are:

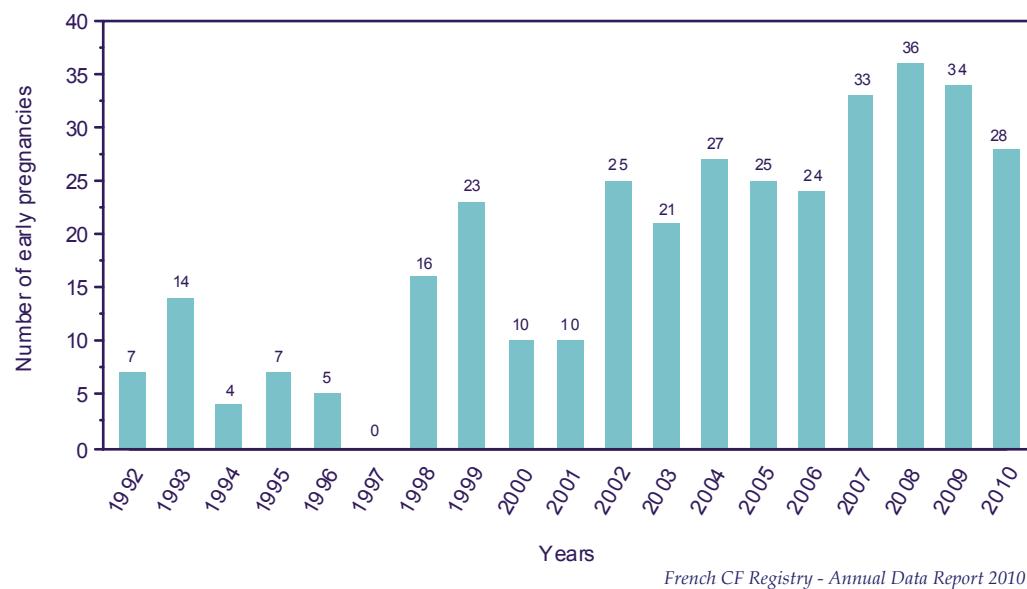

- Births from 1992 to 1996 (in 2010 this cohort was followed during 19 years maximum) : 922 patients, 48 deaths,
- Births from 1997 to 2001 (maximum 14 years of follow up) : 953 patients, 18 deaths,
- Births from 2002 to 2006 (maximum 9 years of follow up) : 997 patients, 7 deaths,
- Births from 2007 to 2010 (maximum 4 years of follow up) : 675 patients, 4 deaths.

There is no significative survival difference between those cohorts (Log-Rank test = 4,94, p = 0,177).

Survival analysis by genotype and sex are available on annex 2.

Pregnancy

Figure 5. Annual number of early pregnancies, evolution since 1992**Table 5. Early pregnancy characteristics**

Characteristics	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010

Symptoms (excluding MI) - Mean age (years)	19.2	20.2	19.2

French CF Registry - Annual Data Report 2010

Notes :

- (a) Including family history and antenatal diagnosis.
- (b) Patients diagnosed before the results of neonatal screening were excluded.

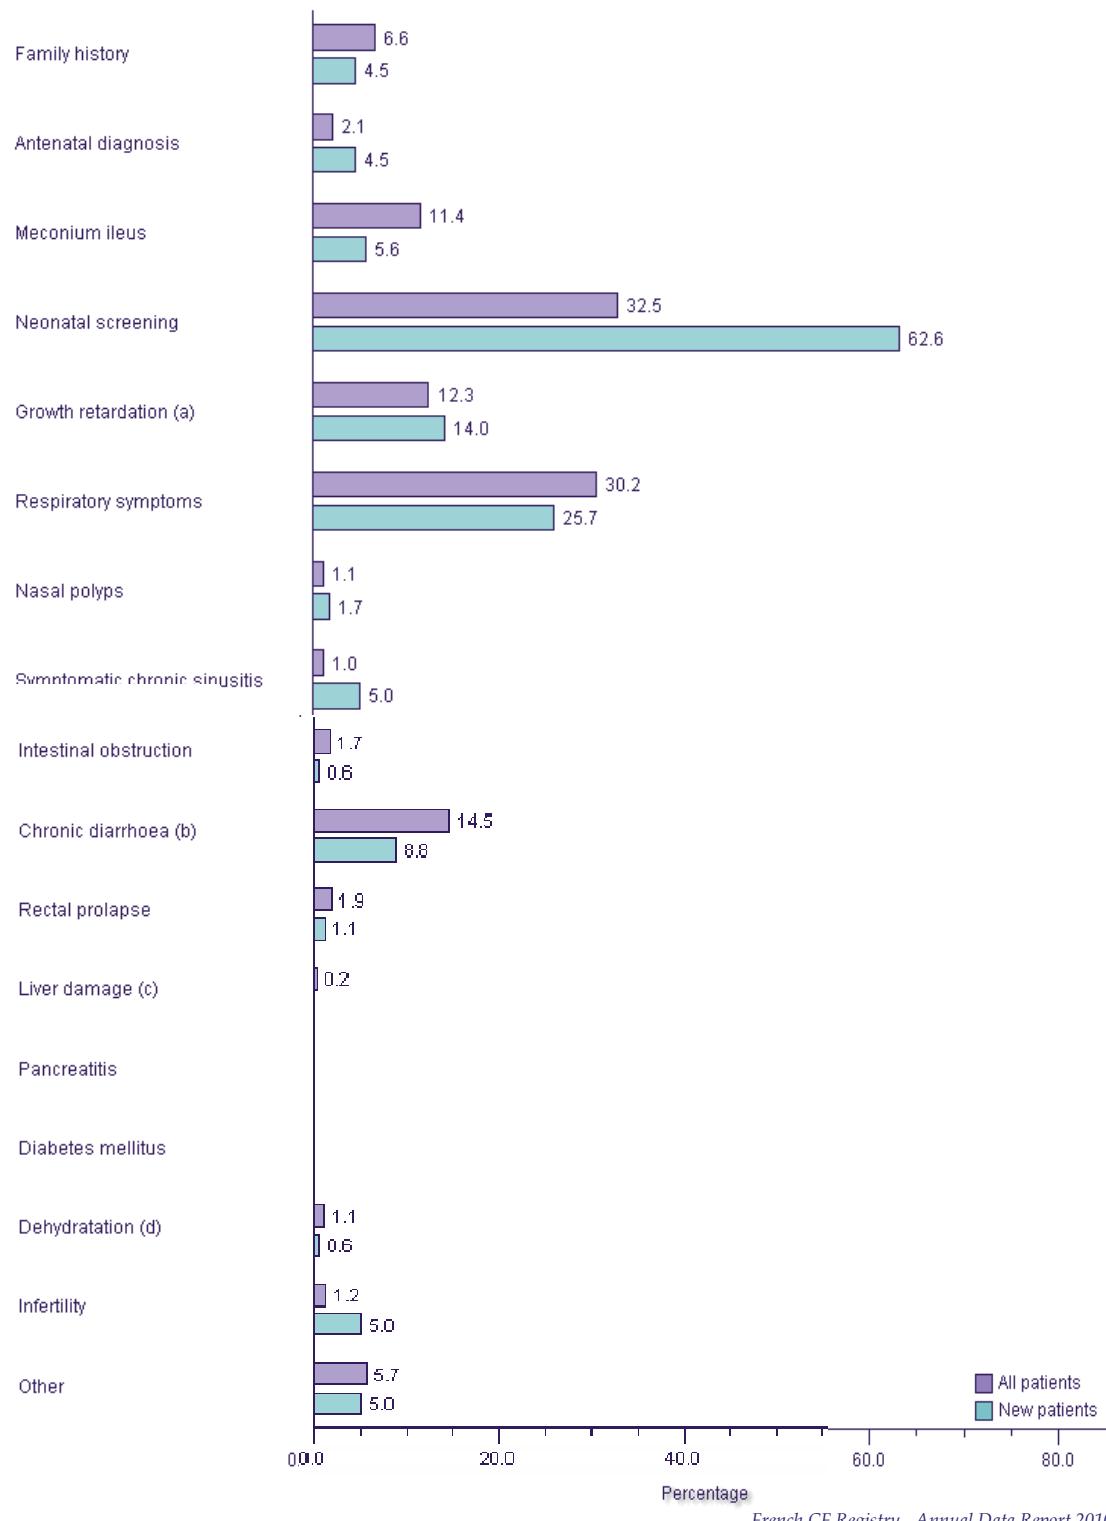

Among the 181 new patients, 111 were born in 2010. The method used to compile this report (patients seen in a care centre in 2010) means that infants born in 2010 and seen for the first time in 2011 are excluded (cf note page 7).

The number of patients diagnosed by neonatal screening (112) given in this report is not the total for France, but represents the patients for whom screening resulted in diagnosis. Patients diagnosed with CF before the screening result was known, (e.g. through meconium ileus), are not included in the total.

Diagnosis

Diagnosis signs

Figure 7. Diagnosis signs

French CF Registry - Annual Data Report 2010

Anthropometry

Height and Weight

Figure 8. Mean height z-scores, by age and sex**Figure 9. Mean weight z-scores, by age and sex**

Height and weight z-scores have been calculated with respect to the French reference population (Sempé M., 1997, *Auxologie – Méthode et séquences*, Méditions, Lyon, 205 p.).

Anthropometry

■ Body Mass Index (BMI)

Figure 10. Mean BMI z-scores, by age

French CF Registry - Annual Data Report 2010

The z-score is a anthropometric reduced centered variable ($Z = [\text{measure-mean}]/\text{standard deviation}$), adjusted for sex and age; the mean and standard deviation are taken from the French reference population with the same sex and age as the patient. This index measures the difference with population norms and a negative score means growth retardation.

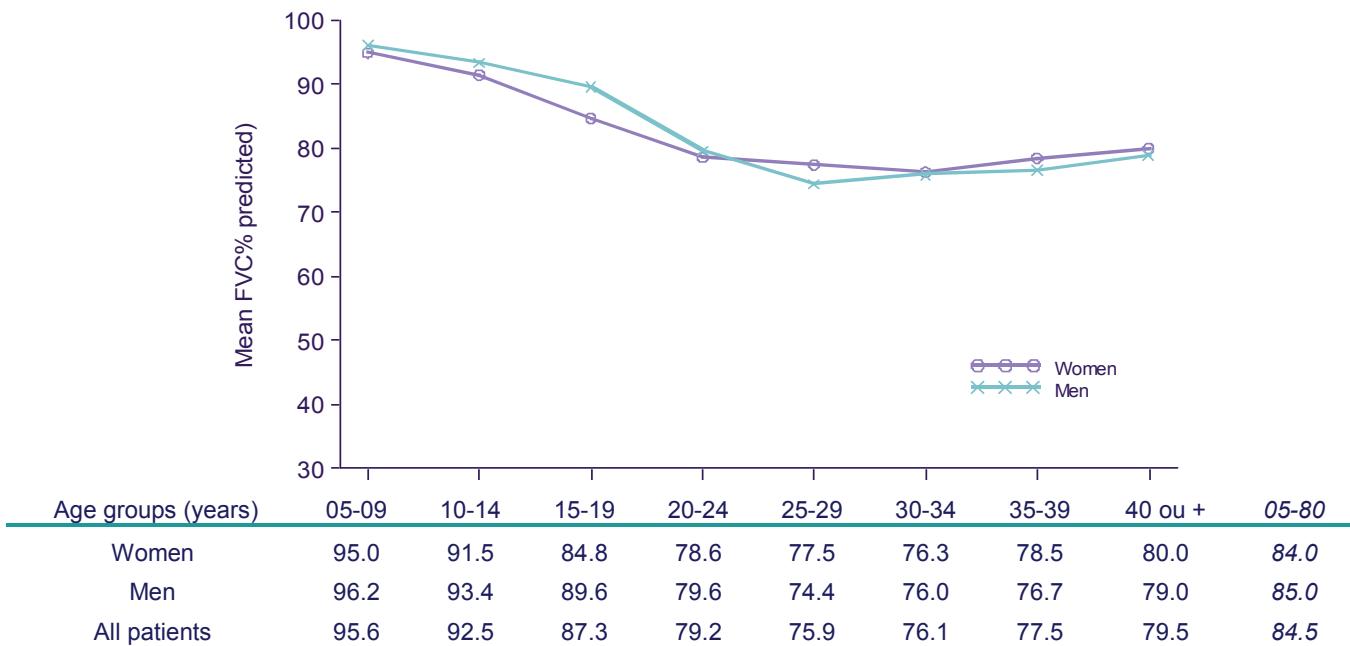

The BMI z-score was calculated with respect to the French reference population (Rolland-Cachera MF et al. A. Body Mass Index variations: centiles from birth to 87 years. Eur J Clin Nutr 1991;45:13-21).

Spirometry

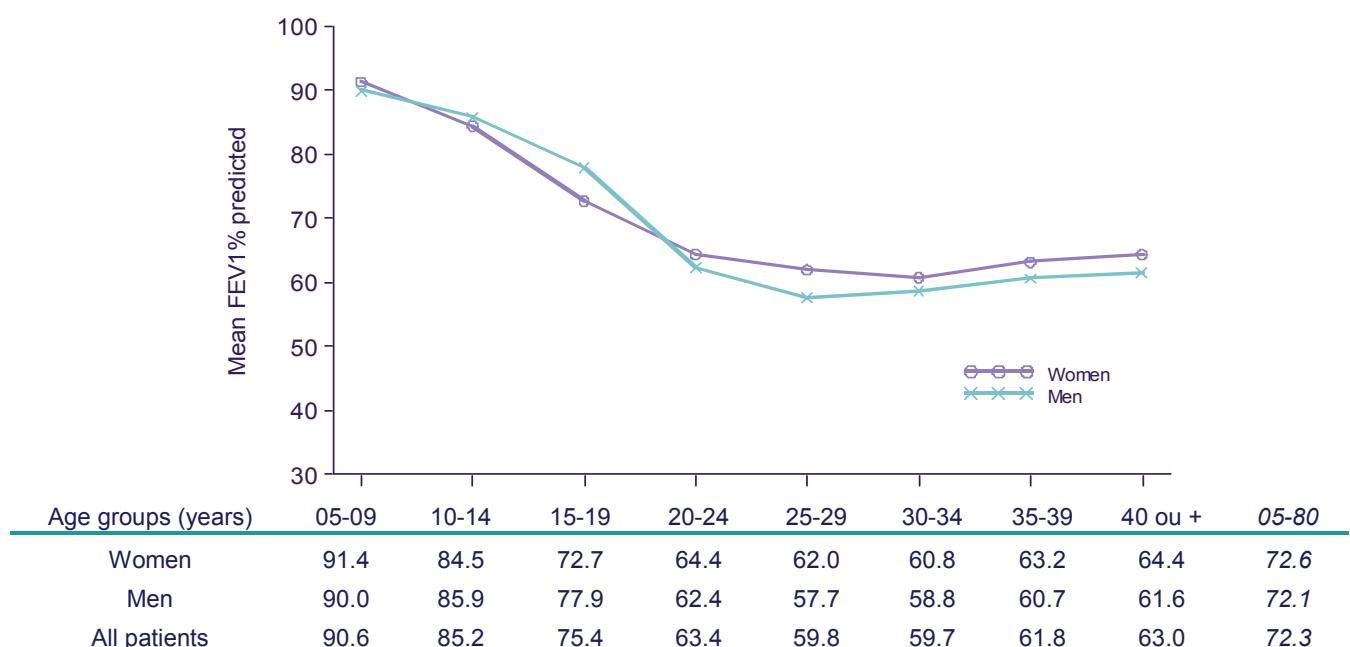

In 2010, 92,4 % of the patients aged 6 or more had at least one spirometry (88,9 % in 2009 and 90,9 % in 2008).

Figure 11. Mean FVC (% predicted), by age

French CF Registry - Annual Data Report 2010

Figure 12. Mean FEV₁ (% predicted), by age

French CF Registry - Annual Data Report 2010

The pulmonary function tests need an active participation of the patient, difficult to obtain before 6 years of age.
The forced vital capacity (FVC) and the forced expiratory volume in the first second (FEV1) are given in % predicted (Knudson *et al.* Changes in the normal maximal expiratory flow-volume curve with growth and aging. *Am Rev Respir Dis* 1983; 127, pp. 725-734).

See appendix 1 for additional information on spirometry and transplantation.

Spirometry

Figure 13. FEV₁ (% predicted) classes

Values of FEV1% predicted are classified in four « functional » groups according to various degrees of bronchial obstruction.

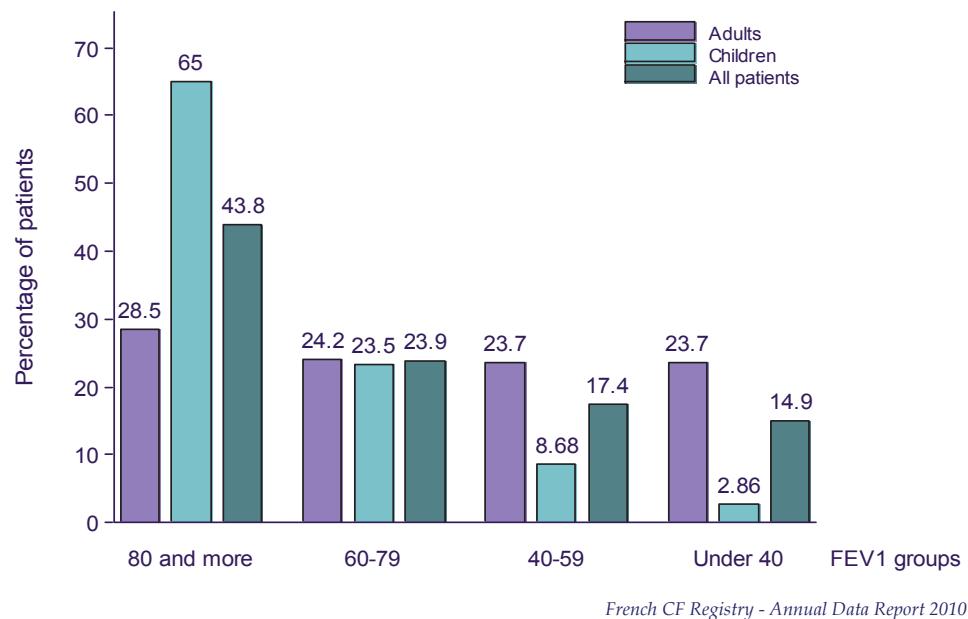

Figure 14. FEV₁ (% predicted) in 2010 compared with 2001, by age

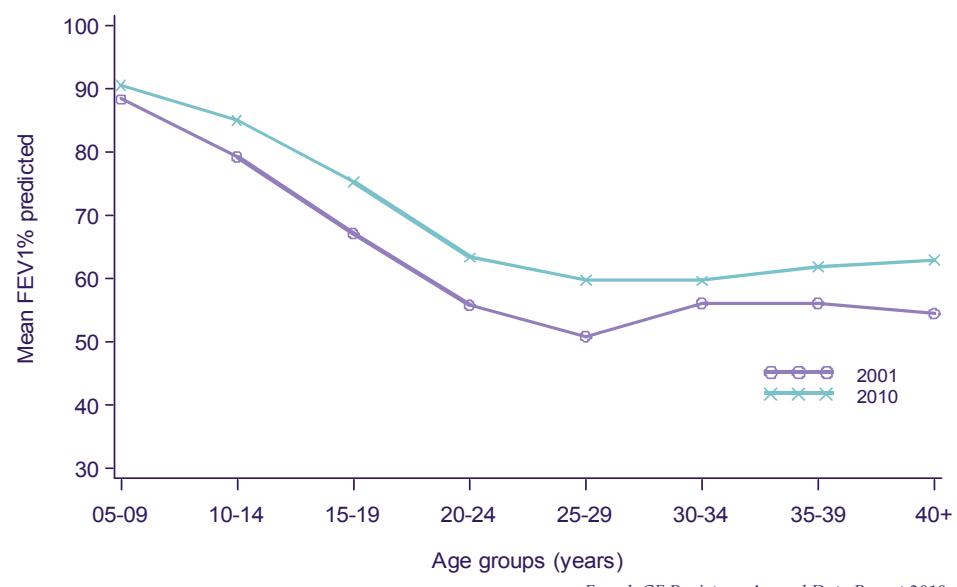

Table 9. Sputum cultures

Patients with at least one sputum	N	Proportion (%)
All patients	5354	93.0 %
Children	2950	97.0 %
Adults	2404	88.4 %

French CF Registry - Annual Data Report 2010

In 2010, 93 % of the patients had at least one sputum culture; this proportion remains steady as it was 92,4 % in 2009 and 92,6 % in 2008. Among the patients without sputum culture (N=404), 46,5 % of them were transplanted.

* Percentage with respect to the entire population.

Chronic colonization: more than 50 % of positive test results in the last 12 months (with at least 4 tests during this period) and/or significant increase in anti-PA antibodies (according to the laboratory).

Multi-resistant colonization: resistant to all the antibiotics in at least two antibiotic classes.

Annex 1

Spirometry and transplantation

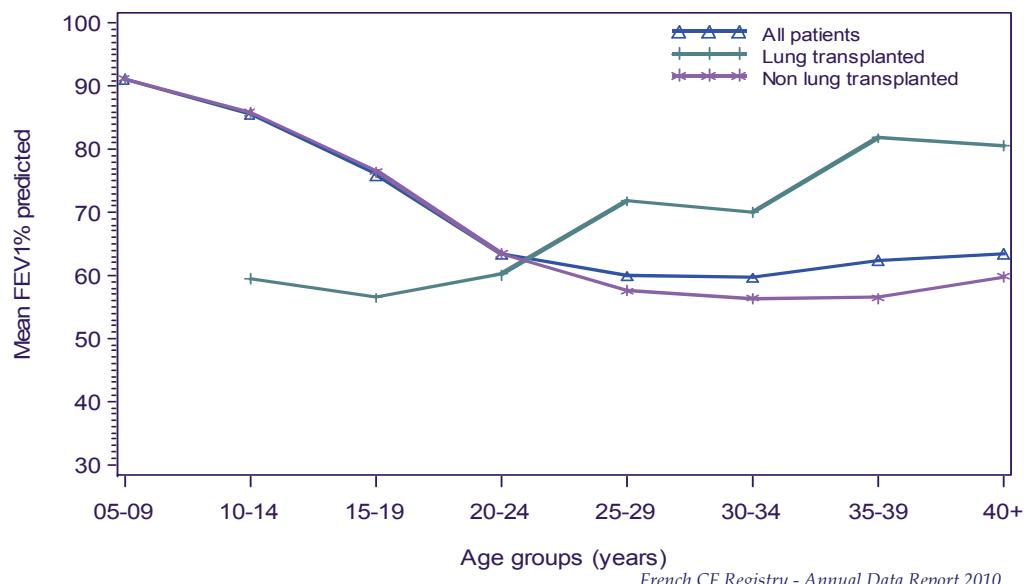

To provide a more comprehensive picture, further comparisons were made using the curves of FEV₁ by age in 2010:

FEV₁ (% predicted) of all patients was compared to that of patients who had or had not received a heart-lung or bilateral lung transplant.

The curves of the whole population and of non-transplanted patients are identical up to age 20-24. After that, FEV₁ (% predicted) of non-transplanted patients drops more sharply than that of the total population, with a difference of almost 7 percentage points at ages 35-39. Among older patients (aged 40 or above) an upward trend is observed for both patient categories, suggesting a selection effect of patients with the mildest forms of CF at these ages.

For patients who had received a lung transplant, for whom the average FEV₁ (% predicted) is available only from ages 10-14, the values are increasing from ages 25-29 up to above 70% of the predicted values.

Figure 32. Mean FEV₁ (% predicted) and transplantation

Annex 2

■ Complement on survival analysis

Two additional survival analysis were performed with the oldest birth cohorts, stratified according to:

1) genotype (figure 33) :

- Births from 1992 to 1996: *F508del/F508del* : 406 patients, 17 deaths; *other genotypes*: 516 patients, 31 deaths
- Births from 1997 to 2001: *F508del/F508del* : 415 patients, 7 deaths; *other genotypes*: 538 patients, 11 deaths

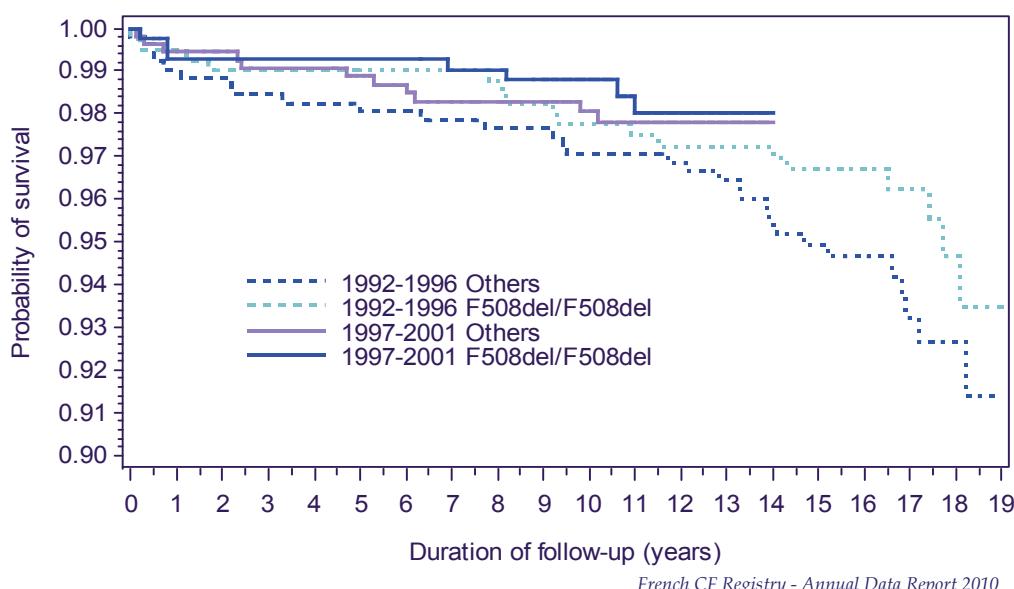

There is no significative survival difference between those cohorts (Log-Rank test = 4,16, p = 0,244).

2) sex (figure 34) :

- Births from 1992 to 1996: *men*: 475 patients, 16 deaths; *women*: 447 patients, 32 deaths
- Births from 1997 to 2001: *men*: 482 patients, 11 deaths; *women*: 471 patients, 7 deaths

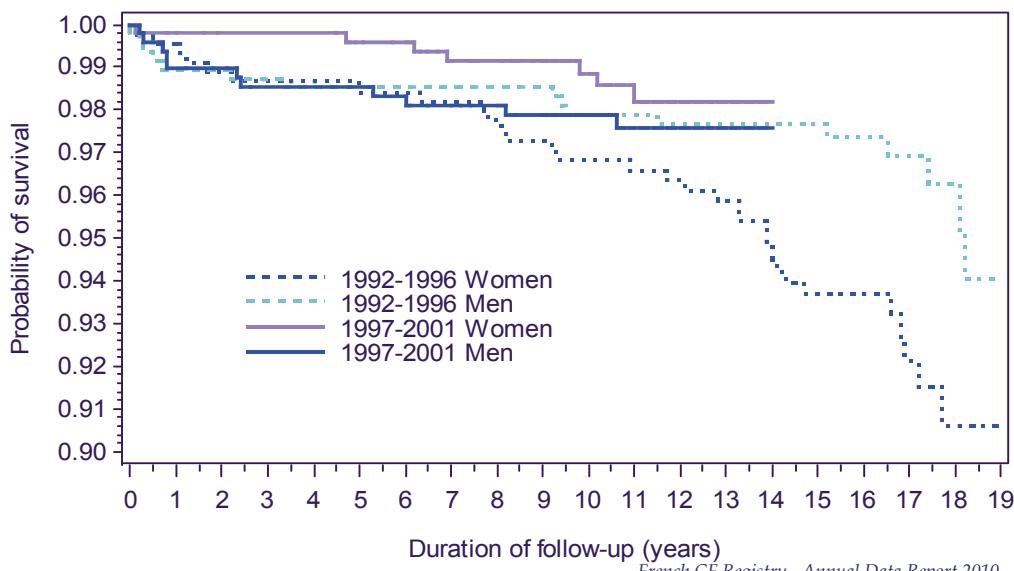

There is a significative survival difference in the 1992-1996 cohorts, men vs women (Log-Rank test = 6,80, p = 0,009) but no difference in the 1997-2001 cohorts.
